Contents

1 Remarks

1.1 Warning!

1. Read every statement!
2. Do not copy-paste without thinking about it.
3. Be careful of overflows! Use long!
4. **Do not trust this document!**

1.2 Operations on bits

1. Check parity of n: `(n & 1) == 0`
2. 2^n: `1L << n.`
3. Test of the ith bit of n is 0: `(n & 1L << i) != 0`
4. Set the ith bit of n at 0: `n &= ~(1L << i)`
5. Set the ith bit of n at 1: `n |= (1L << i)`
6. Union: `a | b`
7. Intersection: `a & b`
8. Subtraction bits: `a & ~b`
9. Verify if n is a power of 2: `(n & (n−1) == 0)`
10. Least significant bit not null of n: `(n & (−n))`
11. Negate: `0 x7fffffff ^n`

1.3 Complexity table

$n \leq$	Maximum complexity
$[10, 11]$	$O(n!), O(n^6)$
$[15, 18]$	$O(2^n n^2)$
$[18, 22]$	$O(2^n n)$
100	$O(n^4)$
400	$O(n^3)$
$2K$	$O(n^2 \log(n))$
$5K$	$O(n^2)$
$1M$	$O(n \log(n))$
$10M$	$O(n), O(\log(n)), O(1)$

Not so obvious complexity: $\sum_{k=1}^{n} \frac{1}{k} = O(\log(n))$

2 Graphs

2.1 Basics

- Adjacency matrix: $A[i][j] = 1$ if i is connected to j and 0 otherwise
- Undirected graph: $A[i][j] = A[j][i] \; \forall \, i, j \; (A = A^T)$
- Adjacency list: `LinkedList<Integer>[] g;` $g[i]$ stores all neighbors of i
- Useful alternatives:

```
HashSet<Integer >[] g; // for edge deletion
HashMap<Integer , Integer >[] g; // for weighted
    graph
```

- Basic classes

```
class Edge implements Comparable<Edge> {
  int o, d, w;
  public Edge(int o, int d, int w) {
    this.o = o; this.d = d; this.w = w;
  }
  public int compareTo(Edge o) {
    return w − o.w;
  }
}
```

2.2 BFS

Computes d, an array of distance from start vertex v. $d[v] = 0$, $d[u] = \infty$ if u not connected to v. If $(u, w) \in E$ and $d[u]$ known and $d[w]$ unknown, $d[w] = d[u] + 1$.

```
int[] bfsVisit(LinkedList<Integer >[] g, int v, int c
    []) { //c is for connected components only
  Queue<Integer> Q = new LinkedList<Integer >();
  Q.add(v);
  int[] d = new int[g.length];
  c[v]=v; //for connected components
  Arrays.fill(d, Integer.MAX_VALUE);
  // set distance to origin to 0
  d[v] = 0;
  while(!Q.isEmpty()) {
    int cur = Q.poll();
    // go over all neighbors of cur
    for(int u : g[cur]) {
      // if u is unvisited
      if(d[u] == Integer.MAX_VALUE) { //or c[u] ==
  −1 if we calculate connected components
        c[u] = v; //for connected components
        Q.add(u);
        // set the distance from v to u
        d[u] = d[cur] + 1;
      }
    }
  }
  return d;
}
```

2.2.1 Connected components

```
int[] bfs(LinkedList<Integer>[] g)
{
  int[] c = new int[g.length];
  Arrays.fill(c, -1);
  for(int v = 0; v < g.length; v++)
    if(c[v] == -1)
      bfsVisit(g, v, c);
  return c;
}
```

2.2.2 Girth

The girth of an undirected graph is the length of its shortest cycle (∞ if none). Complexity $O(|V||E|)$.

```
int girth(LinkedList<Integer>[] g) {
  int girth = Integer.MAX_VALUE;
  for(int v = 0; v < g.length; v++) {
    girth = Math.min(girth, checkFromV(v, g));
  }
  return girth;
}

int checkFromV(int v, LinkedList<Integer>[] g) {
  int[] parent = new int[g.length];
  Arrays.fill(parent, -1);
  int[] d = new int[g.length];
  Arrays.fill(d, Integer.MAX_VALUE);
  Queue<Integer> Q = new LinkedList<Integer>();
  Q.add(v);
  d[v] = 0;
  while(!Q.isEmpty()) {
    int cur = Q.poll();
    for(int u : g[cur]) {
      if(u != parent[cur]) {
        if(d[u] == Integer.MAX_VALUE) {
          parent[u] = cur;
          d[u] = d[cur] + 1;
          Q.add(u);
        } else {
          return d[cur] + d[u] + 1;
        }
      }
    }
  }
  return Integer.MAX_VALUE;
}
```

2.3 DFS

Equals to BFS with *Stack* instead of *Queue* or recursive implementation. Complexity $O(|V| + |E|)$

```
int UNVISITED = 0, OPEN = 1, CLOSED = 2;
boolean cycle; // true iff there is a cycle

void dfsVisit(LinkedList<Integer>[] g, int v,int[]
    label) {
  label[v] = OPEN;
  for(int u : g[v]) {
    if(label[u] == UNVISITED)
      dfsVisit(g, u, label);
    if(label[u] == OPEN)
      cycle = true;
  }
  label[v] = CLOSED;
}

void dfs(LinkedList<Integer>[] g) {
  int[] label = new int[g.length];
  Arrays.fill(label, UNVISITED);
  cycle = false;
  for(int v = 0; v < g.length; v++)
    if(label[v] == UNVISITED)
      dfsVisit(g, v, label);
}
```

2.3.1 Topological order

Graph must be acyclic.

```
Stack<Integer> toposort; // add stack to global
    variables
/* ... */
void dfs(LinkedList<Integer>[] g) {
  /* ... */
  toposort = new Stack<Integer>();
  for(int v = 0; v < g.length; v++) { /* ... */ }
}

void dfsVisit(LinkedList<Integer>[] g, int v,int[]
    label) {
  /* ... */
  toposort.push(v); // push vertex when closing it
  label[v] = CLOSED;
}
```

2.3.2 Strongly connected components

Uses BFS following the topologic order.

```
int[] scc(LinkedList<Integer>[] g) {
  // compute the reverse graph
  LinkedList<Integer>[] gt = transpose(g);
  // compute ordering
  dfs(gt);
  // !! last position will contain the number of scc
    's
  int[] scc = new int[g.length + 1];
  Arrays.fill(scc, -1);
  int nbComponents = 0;
  // simulate bfs loop but in toposort ordering
  while(!toposort.isEmpty()) {
    int v = toposort.pop();
    if(scc[v] == -1) {
      nbComponents++;
      bfsVisit(g, v, scc);
    }
  }
  scc[g.length] = nbComponents;
  return scc;
}
```

2.3.3 SCC, Bridges and Articulation Points in C

C version of SCC (shorter).

```
void tarjanSCC(int u) {
  dfs_low[u] = dfs_num[u] = dfsNumberCounder++; //
    dfs_low[u] <= dfs_num[u]
  S.push_back(u); // stores u in a vector based on
    order of visitation
  visited[u] = 1;
  for(int j = 0; j < (int)AdjList[u].size(); j++) {
    ii v = AdjList[u][j];
    if(dfs_num[v.first] == UNVISITED)
    tarjanSCC(v.first);
    if(visited[v.first]) // condition for update
      dfs_low[u] = min(dfs_low[u], dfs_low[v.first])
    ;
  }
  if(dfs_low[u] == dfs_num[u]) { // if this is a
    root (start) of an SCC
    printf("SCC %d:", ++numSCC); // this part is
    done after recursion
    while(1) {
      int v = S.back(); S.pop_back(); visited[v] =
    0;
      printf(" %d", v);
      if(u == v) break;
    }
    printf("\n");
  }
}
```

```
int main() {
  dfs_num.assign(V, UNVISITED); dfs_low.assign(V, 0)
    ;
  visited.assign(V, 0); dfsNumberCounter = numSCC =
    0;
  for(int i = 0; i < V; i++)
    if(dfs_num[i] == UNVISITED)
      tarjanSCC(i);
}
```

Bridges are edges that, when removed, increases the number of connected components. Articulation points are the same, but for vertices.

```
void articulationPointAndBridge(int u) {
  dfs_low[u] = dfs_num[u] = dfsNumberCounter++; //
    dfs_low[u] <= dfs_num[u]
  for(int j = 0; j < (int)AdjList[u].size(); j++) {
    ii v = AdjList[u][j];
    if(dfs_num[v.first] == UNVISITED) { // a tree
    edge
      dfs_parent[v.first] = u;
      if(u == dfsRoot) rootChildren++; // special
    case if u is a root
      articulationPointAndBridge(v.first);
      if(dfs_low[v.first] >= dfs_num[u]) // for
     articulation point
        articulation_vertex[u] = true; // store this
      information first
      if(dfs_low[v.first] > dfs_num[u]) // for
    bridge
        printf("Edge (%d %d) is a bridge\n", u, v.
    first);
      dfs_low[u] = min(dfs_low[u], dfs_low[v.first])
    ; // update dfs_low[u]
    }
    else if(v.first != dfs_parent[u]) // a back edge
     and not direct cycle
      dfs_low[u] = min(dfs_low[u], dfs_num[v.first])
    ; // update dfs_low[u]
  }
}

int main() {
  dfsNumberCounter = 0; dfs_num.assign(V, UNVISITED)
    ;
  dfs_low.assign(V, 0); dfs_parent.assign(V, 0);
    articulation_vertex.assign(V, 0);
  printf("Bridges:\n");
  for(int i = 0; i < V; i++) {
    dfsRoot = i; rootChildren = 0;
    articulationPointBridge(i);
    articulation_vertex[dfsRoot] = (rootChildren >
    1); // special case
  }
  printf("Articulation Points:\n");
  for(int i = 0; i < V; i++)
    if(articulation_vertex[i])
      printf("Vertex %d\n", i);
}
```

2.3.4 Directed Graph to toposorted DAG

In $O(n+m)$, with Tarjan SCC algo, we merge the SCCs and take the resulting DAG, (remembering their size in scc_size) which is reverse toposorted (i.e. node 0 has no outgoing edge), ready for bottom up DP (starting with node 0 ending with node N) !

```
static Integer[] dfs_num;
static int[] dfs_low, scc_id;
static BitSet visited;
static int dfsNumberCounter;
static Stack<Integer> S;
static void tarjanSCC(LinkedList<Integer>[] g, int u
    , LinkedList< LinkedList<Integer> > SCCs) {
  dfs_low[u] = dfsNumberCounter;
  dfs_num[u] = dfsNumberCounter++; // dfs_low[u] <=
    dfs_num[u]
  S.add(u); // stores u in a vector based on order
    of visitation
  visited.set(u);
  for(int v : g[u]) {
    if(dfs_num[v] == null)
      tarjanSCC(g, v, SCCs);
    if(visited.get(v)) // condition for update
      dfs_low[u] = Math.min(dfs_low[u], dfs_low[v]);
  }
  if(dfs_low[u] == dfs_num[u]) { // if this is a
    root (start) of an SCC
    LinkedList<Integer> newSCC = new LinkedList<
    Integer>();
    int id = SCCs.size();
    for (;;) {
      int v = S.pop(); visited.clear(v);
      newSCC.add(v);
      scc_id[v] = id;
      if(u == v) break;
    }
    SCCs.add(newSCC);
  }
}
static LinkedList<Integer>[] DirectedGraphToDag (
    LinkedList<Integer>[] g) {
  int n = g.length;
  dfs_num = new Integer[n];
  dfs_low = new int[n];
  scc_id = new int[n];
  visited = new BitSet(n);
  dfsNumberCounter = 0;
  S = new Stack<Integer>();
  LinkedList< LinkedList<Integer> > SCCs = new
    LinkedList< LinkedList<Integer> >();
  for(int i = 0; i < n; i++)
    if(dfs_num[i] == null)
      tarjanSCC(g, i, SCCs);
  int N = SCCs.size();
  @SuppressWarnings("unchecked")
  LinkedList<Integer>[] G = new LinkedList[N];
  scc_size = new int[N];
  int i = 0;
  for (LinkedList<Integer> SCC : SCCs) {
    G[i] = new LinkedList<Integer>();
    scc_size[i] = SCC.size();
    BitSet reachable = new BitSet(N);
    reachable.set(i);
    for (int u : SCC) {
      for (int v : g[u])
        if (!reachable.get(scc_id[v])) {
          G[i].add(scc_id[v]);
        }
    }
    i++;
  }
  return G;
}
static int[] scc_size; // bonus information
```

2.4 Minimum Spanning Tree

2.4.1 Prim

```
double prim(LinkedList<Edge>[] g) {
  boolean[] inTree = new boolean[g.length];
  PriorityQueue<Edge> PQ = new PriorityQueue<Edge>()
    ;
  // add 0 to the tree and initialize the priority
    queue
  inTree[0] = true;
  for(Edge e : g[0]) PQ.add(e);
  double weight = 0;
  int size = 1;
  while(size != g.length) {
    // poll the minimum weight edge in PQ
    Edge minE = PQ.poll();
    // if its endpoint in not in the tree, add it
    if(!inTree[minE.d]) {
      // add edge minE to the MST
      inTree[minE.d] = true;
      weight += minE.w;
```

```
      size++;
      // add edge leading to new endpoints to the PQ
      for(Edge e : g[minE.d])
        if(!inTree[e.d]) PQ.add(e);
    }
  }
  return weight;
}
```

2.4.2 Kruskal

Uses Union-Find (See section 8.3).

```
double kruskal(LinkedList<Edge> g, int n) {
  Collections.sort(g);
  UnionFind uf = new UnionFind(n);
  double w = 0;
  int c = 0;
  for(Edge e: g) {
    if(c == n-1) return w;
    if(uf.find(e.o) != uf.find(e.d)) {
      w+=e.w;
      c++;
      uf.union(e.o, e.d);
    }
  }
  return w;
}
```

2.5 Dijkstra

Shortest path from a node v to other nodes. Graph must not have any negative weighted cycle. $O((|V|+|E|)\log(|V|))$

```
double[] dijkstra(LinkedList<Edge>[] g, int v) {
  double[] d = new double[g.length];
  Arrays.fill(d, Double.POSITIVE_INFINITY);
  d[v] = 0;
  PriorityQueue<Edge> PQ = new PriorityQueue<Edge>()
    ;
  for(Edge e : g[v])
    PQ.add(e);
  while(!PQ.isEmpty()) {
    Edge minE = PQ.poll();
    if(d[minE.d] == Double.POSITIVE_INFINITY) {
      d[minE.d] = minE.w;
      for(Edge e : g[minE.dest])
        if(d[e.d] == Double.POSITIVE_INFINITY)
          PQ.add(new Edge(e.o, e.d, e.w + d[e.o]));
    }
  }
  return d;
}
```

2.6 Bellman-Ford

Shortest path from a node v to other nodes. Graph can have negative weighted cycles: Bellman-Ford won't give the correct shortest path, but will warn that a negative cycle exists. $O(|V||E|)$.

```
static double[] bellmanFord(LinkedList<Edge> gt, int
    v, int n) {
  double[] dist = new double[n];
  Arrays.fill(dist, Double.POSITIVE_INFINITY);
  dist[v] = 0;
  for(int i=0; i < n-1; i++)
    for(Edge e : gt)
      if(dist[e.o] + e.w < dist[e.d])
        dist[e.d] = dist[e.o] + e.w;
  for(Edge e : gt)
    if(dist[e.o] + e.w < dist[e.d])
      return null;
  return dist;
}

static double[] spfa (LinkedList<Edge>[] g, int s) {
  int n = g.length;
  double[] dist = new double[n];
  Arrays.fill(dist, Double.POSITIVE_INFINITY);
  Queue<Integer> q = new LinkedList<Integer>();
  BitSet inQueue = new BitSet(n);
  int[] timesIn = new int[n];
  dist[s] = 0;
  q.add(s);
  inQueue.set(s);
  timesIn[s]++;
  while (!q.isEmpty()) {
    int cur = q.poll(); inQueue.clear(cur);
    for (Edge next : g[cur]) {
      int v = next.d, w = next.w;
      if (dist[cur] + w < dist[v]) {
        dist[v] = dist[cur] + w;
        if (!inQueue.get(v)) {
          q.add(v);
          inQueue.set(v);
          timesIn[v]++;
          if (timesIn[v] >= n) {
            return null; // Infinite loop
          }
        }
      }
    }
  }
  return dist;
}
```

2.7 Floyd-Warshall

Shortest path from a node v to other nodes. Graph can have negative weighted cycles: Floyd-Warshall won't give the correct shortest path, but will warn that a negative cycle exists. Negative weighted cycles exists iif $result[v][v] < 0$. $O(|V|^3)$ in time and $O(|V|^2)$ in memory.

```
double[][] floydWarshall(double[][] A)
{
  int n = A.length;
  for(int k = 0; k < n; k++)
    for(int v = 0; v < n; v++)
      for(int u = 0; u < n; u++)
        A[v][u] = Math.min(A[v][u], A[v][k] + A[k][u
    ]);
        //or:
        A[v][u] = min(A[v][u], max(A[v][k], A[k][u])
    ); //minimax
        A[v][u] = max(A[v][u], min(A[v][k], A[k][u])
    ); //maximin
        A[v][u] = max(A[v][u], A[v][k] * A[k][u]);
    //safest path (A contains probability)
  return A;
}
```

2.8 Directed Max flow

2.8.1 Edmonds-Karps (BFS)

Path in residual graph searched via BFS. $O(|V||E|^2)$.

```
int maxflowEK(TreeMap<Integer, Integer>[] g, int
    source, int sink) {
  int flow = 0;
  int pcap;
  while((pcap = augmentBFS(g, source, sink)) != -1)
    {
    flow += pcap;
  }
  return flow;
}

int augmentBFS(TreeMap<Integer, Integer>[] g, int
    source, int sink) {
  // initialize bfs
  Queue<Integer> Q = new LinkedList<Integer>();
  Integer[] p = new Integer[g.length];
```

```java
  int[] pcap = new int[g.length];
  pcap[source] = Integer.MAX_VALUE;
  p[source] = -1;
  Q.add(source);
  // compute path
  while(p[sink] == null && !Q.isEmpty()) {
    int u = Q.poll();
    for(Entry<Integer, Integer> e : g[u].entrySet())
      {
      int v = e.getKey();
      if(e.getValue() > 0 && p[v] == null) {
        p[v] = u;
        pcap[v] = Math.min(pcap[u], e.getValue());
        Q.add(v);
      }
    }
  }
  if(p[sink] == null) return -1;
  // update graph
  int cur = sink;
  while(cur != source) {
    int prev = p[cur];
    int cap = g[prev].get(cur);
    g[prev].put(cur, cap - pcap[sink]);
    Integer backcap = g[cur].get(prev);
    g[cur].put(prev, backcap == null? pcap[sink] :
    backcap + pcap[sink]);
    cur = prev;
  }
  return pcap[sink];
}
```

2.8.2 Ford-Fulkerson

Equals to Edmonds-Karps, but with a DFS. $O(|E|f^*) = O(|V||E|^2)$ where f^* is the value of the max flow.

```java
int pcap;

int maxflowFF(TreeMap<Integer, Integer>[] g, int
    source, int sink) {
  int flow = 0;
  pcap = Integer.MAX_VALUE;
  while(augmentDFS(g, source, sink, new boolean[g.
    length])) {
    flow += pcap;
    pcap = Integer.MAX_VALUE;
  }
  return flow;
}

boolean augmentDFS(TreeMap<Integer, Integer>[] g,
    int cur, int sink, boolean[] done) {
  if(cur == sink) return true;
  if(done[cur]) return false;
  done[cur] = true;
  for(Entry<Integer, Integer> e : g[cur].entrySet())
     {
    if(e.getValue() > 0) {
      int oldcap = pcap;
      pcap = Math.min(pcap, e.getValue());
      if(augmentDFS(g, e.getKey(), sink, done)) {
        g[cur].put(e.getKey(), e.getValue() - pcap);
        Integer backcap = g[e.getKey()].get(cur);
        g[e.getKey()].put(cur, backcap == null? pcap
     : backcap + pcap);
        return true;
      } else {
        pcap = oldcap;
      }
    }
  }
  return false;
}
```

2.8.3 Min cut

We search, between two nodes s and t, subsets of nodes V_1 and V_2 so as $s \in V_1$, $t \in V_2$ and $\sum_{e \in E(V_1,V_2)} w(e)$ minimum.

We just have to compute the max-flow between s and t and to apply a BFS/DFS on the residual graph. All node which are visited are in V_1, others in V_2. The weight from the cut is the max-flow.

2.8.4 Maximum number of disjoint paths

For edge disjoint paths just compute the max flow with unit capacities. For vertex disjoint paths split vertices into two with unit capacity edge between them.

2.8.5 Maximum weighted bipartite matching

Assignment problem: Given a set of n persons and n jobs, and a cost matrix M, assign a job to each person such that the sum of the costs is minimized. It also works for n persons and m jobs with $n \neq m$. Just fill make a square matrix using dummy values. Can also be solve with min cost max flow but it is slower.

$O(n^3)$ solution:

```java
static int[][] cost;
static int n;
static int[] lx, ly;
static int maxMatch;
static boolean[] S, T;
static int[] slack, slackx, prev, xy, yx;

static int[] minHungarian(int[][] M) {
  for(int i = 0; i < M.length; i++)
    for(int j = 0; j < M.length; j++)
      M[i][j] = -M[i][j];
  return maxHungarian(M);
}

static int[] maxHungarian(int[][] M) {
  cost = M;
  n = cost.length;
  slack = new int[n];
  slackx = new int[n];
  prev = new int[n];
  xy = new int[n];

    }
    if (y < n) {break;}
    updateLabels();
    wr = rd = 0;
    for (y = 0; y < n; y++) {
      if (!T[y] && slack[y] == 0) {
        if(yx[y] == -1) {
          x = slackx[y];
          break;
        } else {
          T[y] = true;
          if(!S[yx[y]]) {
            q[wr++] = yx[y];
            addToTree(yx[y], slackx[y]);
          }
        }
      }
    }
    if(y < n) {break;}
  }
  if(y < n) {
    maxMatch++;
    for(int cx=x, cy=y, ty; cx!=-2; cx=prev[cx], cy=
    ty){
      ty = xy[cx];
      yx[cy] = cx;
      xy[cx] = cy;
    }
    augment();
  }
}

static void updateLabels() {
  int delta = Integer.MAX_VALUE;
  for(int y = 0; y < n; y++)
    if(!T[y])
      delta = Math.min(delta, slack[y]);
  for(int i = 0; i < n; i++) {
    if(S[i]) {lx[i] -= delta;}
    if(T[i]) {ly[i] += delta;}
    if(!T[i]) {slack[i] -= delta;}
  }
}

static void addToTree(int x, int prevx) {
  S[x] = true;
  prev[x] = prevx;
  for(int y = 0; y < n; y++) {
    if(lx[x] + ly[y] - cost[x][y] < slack[y]) {
      slack[y] = lx[x] + ly[y] - cost[x][y];
      slackx[y] = x;
    }
  }
}
```

$O(n2^n)$ solution using DP (very simple to code):

```java
int n;
double[][] w;
Double[] memo;

double minCostMatching(int paired) {
  if(memo[paired] != null) return memo[paired];
  if(paired == (1 << n) - 1) return 0.0;
  double min = Double.POSITIVE_INFINITY;
  int i = 0;
  while(((paired >> i) & 1) == 1) i++;
  for(int j = i + 1; j < n; j++) {
    if(((paired >> j) & 1) == 0) {
      min = Math.min(min, w[i][j] + minCostMatching(
    paired | (1 << i) | (1 << j)));
    }
  }
  memo[paired] = min;
  return min;
}
```

2.9 Directed Min cost flow

Avoiding parallel edges: use preprocess to split nodes.

```java
TreeMap<Integer,Edge>[] preprocess(TreeMap<Integer,
    Edge>[] g) {
  TreeMap<Integer, Edge>[] h =
  new TreeMap[2*g.length];
  for(int v = 0; v < h.length; v++)
    h[v] = new TreeMap<Integer, Edge>();
  for(int v = 0; v < g.length; v++) {
    for(Entry<Integer,Edge> entry:g[v].entrySet()) {
      int u = entry.getKey();
      Edge e = entry.getValue();
      h[2*v+1].put(2*u, e);
    }
    h[2*v].put(2*v+1, new Edge(Integer.MAX_VALUE,0))
    ;
  }
  return h;
}
```

Min cost flow analogous to max flow but using Bellman-Ford to find paths (can be made faster using Dijkstra by chaining costs).

```java
int[] p;

int minCostFlow(TreeMap<Integer, Edge>[] g, int s,
    int t) {
  int mincost = 0;
  while(spfa(g, s) != null && p[t] != -1) {
    // compute path capacity
    int cur = t;
    int pcap = Integer.MAX_VALUE;
    while(cur != s) {
      int prev = p[cur];
      pcap = Math.min(pcap, g[prev].get(cur).cap);
      cur = prev;
    }
    // update graph
    cur = t;
    int pcost = 0;
    while(cur != s) {
      int prev = p[cur];
      Edge epath = g[prev].get(cur);
      pcost += epath.cost * pcap;
      // update current edge
      if(epath.cap == pcap) g[prev].remove(cur);
      else epath.cap -= pcap;
      // update reverse edge
      Edge eback = g[cur].get(prev);
      if(eback != null) eback.cap += pcap;
      else g[cur].put(prev, new Edge(pcap, -epath.
    cost));
      cur = prev;
    }
    mincost += pcost;
```

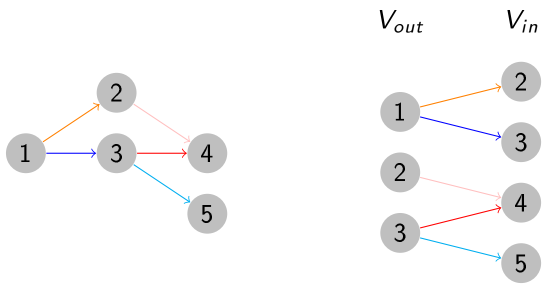
```
    }
    return mincost;
}
```

Some changes to SPFA may be necessary. Computation of global variable p containing parents is required.

2.10 DAG path cover

2.10.1 Cover vertex: disjoint paths

Build a bipartite graph as in the picture:



And compute the maximum bipartite matching. If the number of vertices is n and the matching is m then the answer is $n - m$.

2.10.2 Cover vertex: non-disjoint

Same algorithm but on the transitive closure. Transitive closure is the graph same graph with (v, u) conntected if there is a path from v to u.

2.10.3 Cover edges: disjoint

No flow. This formula gives the number of paths:

$$\sum_{v \in V} \max\left(\textit{out-degree}(v) - \textit{in-degree}(v), 0\right)$$

2.11 Max-Flow with demands

2.11.1 Node demande

Intead of conservation constraints we have for all $v \in V$:

$$\textit{flow-in}(v) - \textit{flow-out}(v) = d_v$$

Add a node s^* connected to each node v with $d_v < 0$ with an edge of capacity $-d_v$. Add a node t^* and connect each node with $d_v > 0$ to it with and edge of capacity d_v. Solution exists iff

$$\textit{max-flow}(s^*, t^*) = \textit{in-capacity}(t^*)$$

2.11.2 Edge lower bounds

Add lower bound l_e to each edge. Constraint becomes

$$l_e \leq f(e) \leq c_e$$

To change into max-flow: (1) define

$$L_v = \sum_{e \text{ into } v} l_e - \sum_{e \text{ out of } v} l_e;$$

(2) set demands $d'_v = d_v - L_v$ where d_v are the input demands (usually 0); (3) set $c'_e = c_e - l_e$; (4) solve max flow with node demands d'_v and capacities c'_e.

2.12 Chinese Postman Problem

Given an undirected weighted graph, compute the minimum length tour that visits every edge (edges may be visited several times, unavoidable if odd degree vertices exist). The number of odd degree vertices is even. Hence we can compute the minimum weight bipartite matching between them where w_{ij} is the length of the shortest path between i and j. Then the length of the tour is given by the sum of the lengths of all edges plus the weight of the matching.

2.13 Bipartite graph

Check if bipartite

```
boolean isBipartite(LinkedList<Integer>[] g)
{
    int[] d = bfs(g);
    for(int u = 0; u < g.length; u++)
        for(Integer v: g[u])
            if((d[u]%2)!=(d[v]%2)) return false;
    return true;
}
```

2.13.1 Max Cardinality Bipartite Matching (MCBM)

Pairing of adjacent nodes. No node in two different pairs.

- Max Flow.
- Augmenting Path: path starting at non matched, ending at non-matched, even edges are matching. MCBM ssi no augmenting path. Start from non-matched, if augmenting path, augment (do not have to take all matching in the augmenting path).

MCBM : Number of matching.

Hungarian algorithm $O(|V||E|)$:

```
static int n; // V
static int m; // vertex on the left subset of V
static LinkedList<Integer>[] g;
static int[] match;
static BitSet visited;

private static int Aug(int left) {
    if (visited.get(left)) return 0;
    visited.set(left);

    for (int right : g[left]) {
        if (match[right] == -1 || Aug(match[right]) ==
        1) {
            match[right] = left;
            return 1; // we found one matching
        }
    }

    return 0; // no matching
}

static int hungarian () {
    int MCBM = 0;
    match = new int[n];
    for (int i = 0; i < n; i++) {
        match[i] = -1;
    }
    for (int l = 0; l < m; l++) {
        visited = new BitSet(n);
        MCBM += Aug(l);
    }
    return MCBM;
}
```

Hopcroft-Karp algorithm $O(\sqrt{|V|}|E|)$:

```java
static int n;
static LinkedList<Integer>[] g;
static Integer[] match;
static int INF;
static int[] dist;
static BitSet left;

static boolean BFS () {
  Queue<Integer> q = new LinkedList<Integer>();
  dist = new int[n];
  for (int u = 0; u < n; u++) {
    if (left.get(u)) {
      if (match[u] == null) {
        dist[u] = 0;
        q.add(u);
      } else
        dist[u] = INF;
    }
  }
  int found = INF;
  while (!q.isEmpty()) {
    int u = q.poll();
    if (dist[u] < found) {
      for (int v : g[u]) {
        if (match[v] == null) {
          if (found == INF)
            found = dist[u] + 1;
        } else if (dist[match[v]] == INF) {
          dist[match[v]] = dist[u] + 1;
          q.add(match[v]);
        }
      }
    }
  }
  return found != INF;
}

static boolean DFS (Integer u) {
  if (u != null) {
    for (int v : g[u]) {
      if (match[v] == null || dist[match[v]] == dist
[u] + 1)
        if (DFS(match[v])) {
          match[v] = u;
          match[u] = v;
          return true;
        }
    }
    dist[u] = INF;
    return false;
  }
  return true;
}

static void left_right () {
  BitSet vis = new BitSet(n);
  left = new BitSet(n);
  Queue<Integer> q = new LinkedList<Integer>();
  for (int i = 0; i < n; i++) {
    if (vis.get(i)) continue;
    vis.set(i);
    left.set(i);
    q.add(i);
    while (!q.isEmpty()) {
      int cur = q.poll();
      for (int next : g[cur]) {
        if (!vis.get(next)) {
          vis.set(next);
          if (!left.get(cur))
            left.set(next);
          q.add(next);
        }
      }
    }
  }
}

static int hopcroftKarp () {
  left_right();
  INF = n+1;
  match = new Integer[n];
  int MCBM = 0;
  while (BFS())
    for (int u = 0; u < n; u++)
      if (left.get(u) && match[u] == null)
        if (DFS(u))
          MCBM++;
  return MCBM;
}
```

2.13.2 Independent Set (or Dominating Set)

Set of vertices with no edges between them. MIS, add a vertex create an edge. In **bipartite** graph, MIS + MCBM = V.

2.13.3 Vertex Cover

Vertices such that each edge is adjacent to at least one vertex. Min Vertex Cover (MVC). In **bipartite** graph, MVC = MCBM. In **general** graph, MIS + MVC = $|V|$ and the MVC is the complementary of MIS.

3 Dynamic programming

3.1 Bottom-up

Give n objects of value $v[i]$ to 3 people such that $\max_i V_i - \min_i V_i$ is minimum (V_i is total value for person i).
$canDo[i][v_1][v_2] = 1$ if we can give the objects $0, 1, \dots, i$ such that v_1 is going to P_1 and v_2 to P_2, 0 otherwise. v_3 is determined from the sum.

Base case $i = 0$:

- $canDo[0][0][0] = 1$
- $canDo[0][v[0]][0] = 1$
- $canDo[0][0][v[0]] = 1$

Case $i \geq 1$:
$canDo[i][v_1][v_2] =$
$canDo[i-1][v_1][v_2] \lor$
$canDo[i-1][v_1 - v[i]][v_2] \lor$
$canDo[i-1][v_1][v_2 - v[i]]$

Sol. : $\min_{v_1, v_2 : canDo[n-1][v_1][v_2]} [max(v_1, v_2, S - v_1 - v_2) - min(v_1, v_2, S - v_1 - v_2)]$

```java
int solveDP() {
  boolean[][][] canDo = new boolean[v.length][sum +
    1][sum + 1];
  // initialize base cases
  canDo[0][0][0] = true;
  canDo[0][v[0]][0] = true;
  canDo[0][0][v[0]] = true;
  // compute solutions using recurrence relation
  for(int i = 1; i < v.length; i++) {
    for(int a = 0; a <= sum; a++) {
      for(int b = 0; b <= sum; b++) {
        boolean giveA = a - v[i] >= 0 && canDo[i -
  1][a - v[i]][b];
        boolean giveB = b - v[i] >= 0 && canDo[i -
  1][a][b - v[i]];
        boolean giveC = canDo[i - 1][a][b];
        canDo[i][a][b] = giveA || giveB || giveC;
      }
    }
  }
  // compute best solution
  int best = Integer.MAX_VALUE;
  for(int a = 0; a <= sum; a++) {
    for(int b = 0; b <= sum; b++) {
      if(canDo[v.length - 1][a][b]) {
        best = Math.min(best, max(a, b, sum - a - b)
    - min(a, b, sum - a - b));
      }
    }
  }
  return best;
```

}

3.2 Top-down

Same problem as bottom-up. Main idea : memoization (Remember intermediate results).

```
int solve(int i, int a, int b) {
  if(i == n) {
    memo[i][a][b] = max(a, b, sum - a - b) - min(a,
    b, sum - a - b);
    return memo[i][a][b];
  }
  if(memo[i][a][b] != null) {
    return memo[i][a][b];
  }
  int giveA = solve(i + 1, a + v[i], b);
  int giveB = solve(i + 1, a, b + v[i]);
  int giveC = solve(i + 1, a, b);
  memo[i][a][b] = min(giveA, giveB, giveC);
  return memo[i][a][b];
}
```

3.3 Knapsack problem

Given n objects of value $v[i]$ and weight$w[i]$, an integer W :

- Maximize $\sum_i x[i]v[i]$
- Such that $\sum_i x[i]w[i] \leq W$ where $x[i]$= 0 (not taken) or 1 (taken)

3.3.1 No repetition

best[i][w]= best way to take objects $0, 1, \ldots, i$ in a knapsack of capacity w.

Base case:

- $best[0][w] = v[0]$ si $w[0] \leq w$
- 0 else

Other cases:
$best[i][w] =$
$\max\{best[i-1][w],$
$best[i-1][w - w[i]] + v[i]\}$

3.3.2 An object can be repeated

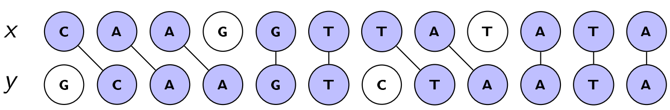
- $best[0] = 0$
- $best[w] = \max_{i:w[i]<w}\{best[w - w[i]] + v[i]\}$

3.3.3 Several knapsacks

$best[i][w_1][w_2]$ = best way to take objects $0, 1, \ldots, i$ in knapsacks of capacity w_1 and w_2.

3.4 Longest common sub-sequence (LCS)

Given two String x and y. Find the longest common subsequence between x and y.



- **Formulation:** $lcs[i][j]$ = size of $LCS(x[0]x[1]\cdots x[i-1], y[0]y[1]\cdots y[j-1])$
- **Base case:** $lcs[0][j] = 0$ $lcs[i][0] = 0$
- **Other cases:**
  - Si $x[i-1] = y[i-1]$ alors: $lcs[i][j] = 1 + lcs[i-1][j-1]$
  - Si $x[i-1] \neq y[i-1]$ alors: $lcs[i][j] = \max\{lcs[i-1][j], lcs[i][j-1]\}$

3.5 Matrix Chain Multiplication (MCM)

Given a list of matrices, find the order minimizing the number of multiplications to compute their product.

- Number to multiply a matrix of size $n \times m$ by a matrix of size $m \times r$: $n \cdot m \cdot r$.
- Example: A : 10×30, B : 30×5 et C : 5×60.
  - For $(AB)C$: $10 \cdot 30 \cdot 5 + 10 \cdot 5 \cdot 60 = 4500$ multiplications.
  - For $A(BC)$: $30 \cdot 5 \cdot 60 + 10 \cdot 30 \cdot 60 = 27000$ multiplications.
- **Formulation :** $best[i][j]$ = min cost to multiply $A_i, \ldots, A_j$
- **Base case :** $best[i][i] = 0$
- **Other cases:**

$$best[i][j] = \min_{i \leq k < j} best[i][k] + best[k+1][j] + A_i.n_1 \times A_k.n_2 \times A_j.n_2$$

3.5.1 Generalized MCM

Given a list of objects $x[0], \ldots, x[n-1]$ and an operation $\odot$ with an associated cost, find the order in which perform the operations to minimize the total cost. The matrix product is replaced by $\odot$.

$$best[i][j] = \min_{i \leq k < j} best[i][k] + best[k+1][j] + cost(i, j, k)$$

$cost(i, j, k)$ is the cost of $(x[i] \odot \cdots \odot x[k]) \odot (x[k+1] \odot \cdots \odot x[j])$.

```
int bestParenthesize() {
  int n = x.length; // x is a global variable
  int[][] best = new int[n][n];
  for(int i = 0; i < n; i++) {
    best[i][i] = 0;
  }
  for(int l = 1; l <= n; l++) {
    for(int i = 0; i < n - l; i++) {
      int j = i + l;
      int min = Integer.MAX_VALUE;
      for(int k = i; k < j; k++) {
        min = Math.min(min, best[i][k] + best[k +
  1][j] + cost(i, j, k)); // cost is problem-
  independent
      }
      best[i][j] = min;
    }
  }
  return best[0][n - 1];
}
```

3.6 Edit distance

Given two String x and y, by performing operations on en x, compute the minimal cost to transform x into y.
We can (operation cost):

1. Remove a character (D=1)
2. Insert a character (I=1)
3. Replace a character(R=2)

- **Formulation**:$editDist[i][j]$= min. cost to transform $x_0 \cdots x_{i-1}$ into $y_0 \cdots y_{j-1}$
- **Base case**:
  $editDist[i][0] = i \cdot D \quad editDist[0][j] = j \cdot I$
- **Other cases**:

$$editDist[i][j] = \min \begin{array}{l} editDist[i-1][j] + D, \\ editDist[i][j-1] + I, \\ editDist[i-1][j-1] + R^* \end{array}$$

where $R^* = R$ if $x[i-1] \neq y[j-1]$, 0 else.

```java
int editDistance(String txt1, String txt2, int I,
    int D, int R){
  int[][] d = new int[txt1.length()+1][txt2.length()
    +1];
  for(int i=0; i <= txt1.length(); i++)
    d[i][0]=i*D;
  for(int j=0; j <= txt2.length(); j++)
    d[0][j]=j*I;
  for(int i=1; i <= txt1.length(); i++){
    for(int j=1; j <= txt2.length(); j++){
      int cost;
      // Non-equality cost
      if(txt1.charAt(i-1)==txt2.charAt(j-1))
        cost = 0;
      else
        cost = R;
      // Deletion, Insertion, Replacement
      d[i][j] = Math.min(Math.min(d[i-1][j] + D, d[i
    ][j-1] + I), d[i-1][j-1] + cost);
    }
  }
  // Last computed element is the edit distance
  return d[txt1.length()][txt2.length()];
}
```

3.7 Suffix array

3.7.1 $O(n\log(n)^2)$, full matrix, need $n \leq 10K$

- Suffix array of $algorithm$ = algorithm, gorithm, hm, ithm, lgorithm, m, orithm, rithm, thm
- Characterized by its starting index
  Example : Suffix array of $algorithm$:

  $$[0,\ 2,\ 7,\ 5,\ 1,\ 8,\ 3,\ 4,\ 6]$$

  Example : Given suf_j suffix beginning at index j, and $C(i,j,k)$ comparison result of suf_j and suf_k on the 2^i first characters.

$$C(i,j,k) = \begin{array}{ll} C(i-1,j,k) & \text{si } C(i-1,j,k) \neq 0 \\ C(i-1,j+2^{i-1},k+2^{i-1}) & \text{else} \end{array}$$

- Define a matrix so such that:

$$so[i][j] = so[i][k] \Leftrightarrow C(i,j,k) = 0$$
$$so[i][j] < so[i][k] \Leftrightarrow C(i,j,k) < 0$$
$$so[i][j] > so[i][k] \Leftrightarrow C(i,j,k) > 0$$

  $so[i]$ is the order of sorted suffixes on the 2^i first characters.

- **Base case:** $so[0][j] = (int)s.charAt(i)$
  Example: for $s = ccacab$ we have
  $s[0] = [97, 97, 95, 97, 95, 96]$
- For every j we define a triplet (l, r, j):

$$\begin{array}{ll} (s[i-1][j], s[i-1][j+2^{i-1}], j) & \text{si } j+2^{i-1} < n \\ (s[i-1][j], -1, j) & \text{si } j+2^{i-1} \geq n \end{array}$$

```java
class Triple implements Comparable<Triple> {
  int l, r, index;
  public Triple(int half1, int half2, int index) {
    this.l = half1;
    this.r = half2;
    this.index = index;
  };
  public int compareTo(Triple other) {
    if(l != other.l) {
      return l - other.l;
    }
    return r - other.r;
  }
}
```

```java
int[][] suffixOrder(String s) { // O(n log^2(n))
  int n = s.length();
  int lg = (int)Math.ceil((Math.log(n) / Math.log(2)
    )) + 1;
  int[][] so = new int[lg][n];
  // initialize so[0] with character order
  for(int i = 0; i < n; i++) {
    so[0][i] = s.charAt(i);
  }
  Triple[] next = new Triple[n];
  for(int i = 1; i < lg; i++) {
    // build the next array
    for(int j = 0; j < n; j++) {
      int k = j + (1 << (i - 1));
      next[j] = new Triple(so[i - 1][j], k < n ? so[
    i - 1][k] : -1, j);
    }
    // sort next array
    Arrays.sort(next);
    // build so[i]
    for(int j = 0; j < n; j++) {
      if(j == 0) {
      // smallest elements gets value 0
      so[i][next[j].index] = 0;
     } else if(next[j].compareTo(next[j - 1]) == 0)
    {
      // equal to previous so it gets the same value
      so[i][next[j].index] = so[i][next[j - 1].index
    ];
     } else {
      // largest than previous so get + 1
      so[i][next[j].index] = so[i][next[j - 1].index
    ] + 1;
      }
    }
  }
  return so;
}
```

4 Geometry in 2D

Be careful of rounding errors. Define E in function of the problem. Double.parseDouble is a lot slower than Integer.parseInt.

```
boolean eq(double a,double b){return Math.abs(a - b)
    <= E;}
boolean le(double a,double b){return a < b - E;}
boolean leq(double a,double b){return a <= b + E;}
```

4.1 Areas

Let D be a simple closed curve and C its boundary. For any function $F(x,y) = (F_1(x,y), F_2(x,y))$ such that $\partial F_2/\partial x - \partial F_1/\partial y = 1$ we have $area(D) = \int_C F(s)ds$. Recall that $\int_C F(s)ds = \int_a^b F(r(t)) \cdot r'(t)dt$ where $r : [a,b] \to C$ is a parametrization of C. Usual parametrization of a line segment (x_1,y_1) to (x_2,y_2): $r(t) = (x_1 + t(x_2-x_1), y_1 + t(y_2-y_1)), t \in [0,1]$. Usual parametrization of a circle arc θ_1 to θ_2: $r(t) = (R\cos(t), R\sin(t)), t \in [\theta_1, \theta_2]$.

Example: Choose for instance $F(x,y) = (0,x)$ we have $\partial F_2/\partial x - \partial F_1/\partial y = \partial x/\partial x - \partial 0/\partial y = 1 - 0 = 1$. For the segment we have:

$$F(r(t)) = (x_1 + t(x_2-x_1), y_1 + t(y_2-y_1)) = (0, x_1 + t(x_2-x_1))$$

$$r'(t) = (x_2 - x_1, y_2 - y_1)$$

The contribution of a line segment is:

$$\begin{aligned}\int_0^1 F(r(t))r'(t)dt &= \int_0^1 (0, x_1 + t(x_2-x_1)) \cdot (x_2-x_1, y_2-y_1) \\ &= \int_0^1 t(x_2-x_1)(y_2-y_1) = \frac{(x_2-x_1)(y_2-y_1)}{2}\end{aligned}$$

For the circle arc we have:

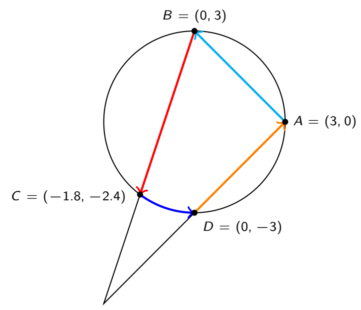
$$F(r(t)) = (R\cos(t), R\sin(t)) = (0, R\cos(t))$$

$$r'(t) = (-R\sin(t), R\cos(t))$$

The contribution of a circle arc is:

$$\begin{aligned}\int_{\theta_1}^{\theta_2} F(r(t))r'(t)dt &= \int_{\theta_1}^{\theta_2} (0, R\cos(t)) \cdot (-R\sin(t), R\cos(t)) \\ &= \int_{\theta_1}^{\theta_2} R^2\cos^2(t) = \frac{R^2}{2}(t + sin(t)cos(t))\Big|_{\theta_1}^{\theta_2} \\ &= \frac{R^2}{2}(\theta_2 + sin(\theta_2)cos(\theta_2) - \theta 1 - sin(\theta_1)cos(\theta_1))\end{aligned}$$

intersection area = 4.5 + 4.86 + 0.74 + 4.5



4.2 Vectors

4.2.1 Rotation around (0,0)

$(x,y) \leftrightarrow x + yi$
$\rho e^{i\theta} = \rho\cos(\theta) + i\rho\sin(\theta)$

(x,y) rotated by α is $(\cos(\alpha)x - \sin(\alpha)y, \sin(\alpha)x + \cos(\alpha)y)$

4.3 Points

```
class Point implements Comparable<Point>
{
  double x, y;
  public int compareTo(Point o) { //xcomp
    if(a.x < b.x) return -1;
    if(a.x > b.x) return 1;
    if(a.y < b.y) return -1;
    if(a.y > b.y) return 1;
    return 0;
  }
}
```

```
class yComp implements Comparator<Point> {
  public int compare(Point p, Point q) {
    if(p.y == q.y) {return Double.compare(p.x, q.x)
    ;}
    return Double.compare(p.y, q.y);
  }
}
```

4.3.1 Point in box

```
boolean inBox(Point p1, Point p2, Point p) {
  return Math.min(p1.x, p2.x) <= p.x && p.x <= Math.
    max(p1.x, p2.x) &&
         Math.min(p1.y, p2.y) <= p.y && p.y <= Math.
    max(p1.y, p2.y);
}
```

4.3.2 Polar sort

```
LinkedList<Point> sortPolar(Point[] P, Point o)
{
  LinkedList<Point> above = new LinkedList<Point>();
  LinkedList<Point> samePos = new LinkedList<Point
    >();
  LinkedList<Point> sameNeg = new LinkedList<Point
    >();
  LinkedList<Point> bellow = new LinkedList<Point>()
    ;
  for(Point p : P)
  {
    if(p.y > o.y)
      above.add(p);
    else if(p.y < o.y)
      bellow.add(p);
    else
    {
      if(p.x < o.x)
        sameNeg.add(p);
      else
        samePos.add(p);

    }
  }
  PolarComp comp = new PolarComp(o);
  Collections.sort(samePos, comp);
  Collections.sort(sameNeg, comp);
  Collections.sort(above, comp);
  Collections.sort(bellow, comp);
  LinkedList<Point> sorted = new LinkedList<Point>()
    ;
  for(Point p : samePos) sorted.add(p);
  for(Point p : above) sorted.add(p);
  for(Point p : sameNeg) sorted.add(p);
  for(Point p : bellow) sorted.add(p);
  return sorted;
}

class PolarCmp implements Comparator<Point> {
  static Point orig = new Point(0, 0);
  public int compare(Point p, Point q) {
    double o = orient(orig, p, q);
    if(o == 0) {
      if(p.x * p.x + p.y * p.y > q.x * q.x + q.y * q
    .y)
        return 1;
      return -1;
    }
    return -(int)Math.signum(o);
  }
}
```

4.3.3 Closest pair of points

```
double closestPair(Point[] points) {
  if(points.length == 1) {return Double.
    POSITIVE_INFINITY;}
  Arrays.sort(points, new xComp());
  double min = dist(points[0], points[1]);
  // keep track of the leftmost point
  int leftmost = 0;
  TreeSet<Point> candidates = new TreeSet<Point>(new
     yComp());
  candidates.add(points[0]);
  candidates.add(points[1]);
  for(int i = 2; i < points.length; i++) {
    Point cur = points[i];
    // eliminate points s.t cur.x - x > min
    while(cur.x - points[leftmost].x > min) {
      candidates.remove(points[leftmost]);
      leftmost++;
    }
    Point low = new Point(0, cur.y - min);
    Point high = new Point(0, cur.y + min);
    // check all points in the rectangle
    for(Point point : candidates.subSet(low, high))
      min = Math.min(min, dist(cur, point));
    candidates.add(cur);
  }
  return min;
}
```

4.3.4 Orientation

$$orient(p,q,r) = \begin{vmatrix} 1 & p_x & p_y \\ 1 & q_x & q_y \\ 1 & r_x & r_y \end{vmatrix}$$

$$orient(p,q,r) \begin{cases} = 0 & p,q,r \text{ are collinear} \\ < 0 & p \text{ -> } q \text{ -> } r \text{ is clockwise} \\ > 0 & p \text{ -> } q \text{ -> } r \text{ is counterclockwise} \end{cases}$$

$$|orient(p,q,r)| = 2 \cdot area \triangle(p,q,r)$$

```
double orient(Point p, Point q, Point r) {
  return q.x * r.y - r.x * q.y - p.x * (r.y - q.y) +
     p.y * (r.x - q.x);
}
```

4.3.5 Angle visibility

x lies strictly inside the angle formed by p, q, r iff

$$sgn(orient(p,q,x)) = sgn(orient(p,x,r))$$
$$sgn(orient(p,r,x)) = sgn(orient(p,x,q))$$

To allow it to lie on the border simply check if

$$sgn(orient(p,q,x)) = 0 \text{ or } sgn(orient(p,r,x)) = 0$$

4.3.6 Fixed radius neighbors (1D)

```
List<Double[]> findPairs1D(double[] x, double r) {
  HashMap<Integer, List<Double>> H = new HashMap<
    Integer, List<Double>>();
  // fill buckets
  for(int i = 0; i < x.length; i++) {
    int b = (int)(x[i] / r);
    if(H.containsKey(b)) {
      H.get(b).add(x[i]);
    } else {
      List<Double> L = new ArrayList<Double>();
      L.add(x[i]);
      H.put(b, L);
    }
  }
  // find pairs in consecutive buckets
  List<Double[]> pairs = new LinkedList<Double[]>();
  for(int i = 0; i < x.length; i++) {
    int b = (int)(x[i] / r);
    List<Double> bucket = H.get(b + 1);
    if(bucket != null)
      for(double y : bucket)
        if(y - x[i] <= r)
          pairs.add(new Double[] {x[i], y});
  }
  // add points in buckets
  for(List<Double> bucket : H.values())
    for(int i = 0; i < bucket.size(); i++)
      for(int j = i + 1; j < bucket.size(); j++)
        pairs.add(new Double[] {bucket.get(i),
    bucket.get(j)});
  return pairs;
}
```

4.3.7 Fixed radius neighbors (2D)

```java
List<Point[]> findPairs2D(Point[] points, double r)
  {
  HashMap<Integer, List<Point>> H = new HashMap<
    Integer, List<Point>>();
  // fill buckets
  for(int i = 0; i < points.length; i++) {
    int bx = (int)(points[i].x / r);
    int by = (int)(points[i].y / r);
    int key = 33 * bx + by;
    if(H.containsKey(key)) {
      H.get(key).add(points[i]);
    } else {
      List<Point> L = new ArrayList<Point>();
      L.add(points[i]);
      H.put(key, L);
    }
  }
  // find pairs in adjacent buckets
  List<Point[]> pairs = new LinkedList<Point[]>();
  int[][] dir = new int[][] {new int[] {1,0}, new
    int[] {0,1}, new int[] {1,1}};
  for(int i = 0; i < points.length; i++) {
    int bx = (int)(points[i].x / r);
    int by = (int)(points[i].y / r);
    for(int[] d : dir) {
      List<Point> bucket = H.get(33 * (bx + d[0]) +
  (by + d[1]));
      if(bucket != null)
        for(Point y : bucket)
          if(sqDist(points[i], y) <= r * r)
            pairs.add(new Point[] {points[i], y});
    }
  }
  // add points in buckets
  for(List<Point> bucket : H.values())
    for(int i = 0; i < bucket.size(); i++)
      for(int j = i + 1; j < bucket.size(); j++)
        if(sqDist(bucket.get(i), bucket.get(j)) <= r
   * r)
          pairs.add(new Point[] {bucket.get(i),
    bucket.get(j)});
  return pairs;
}
```

4.4 Lines

General equation: $Ax + By = C$. The line through $(x_1, y_1), (x_2, y_2)$ is given by: $A = y_2 - y_1$, $B = x_1 - x_2$, $C = Ax_1 + By_1$.

4.4.1 Intersections

Intersection exists there is a solution for $A_1x + B_1y = C_1$ and $A_2x + B_2y = C_2$. This happens if and only if

$$d := \det \begin{pmatrix} A_1 & B_1 \\ A_2 & B_2 \end{pmatrix} \neq 0$$

Intersection is given by

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} A_1 & B_1 \\ A_2 & B_2 \end{pmatrix}^{-1} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \frac{1}{d} \begin{pmatrix} B_2 & -B_1 \\ -A_2 & A_1 \end{pmatrix} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix}$$

4.4.2 Perpendicular line

The lines perpendicular to $Ax + By = C$ are

$$-Bx + Ay = D \quad \text{for } D \in \mathbb{R}$$

If we want the one that goes through (x_0, y_0) set

$$D = -Bx_0 + Ay_0$$

4.4.3 Orthogonal Symmetry

For a line, find X', the point which is the orthogonal symmetry of X on line a.
Computes the perpendicular of the given line that goes through X. Compute intersection Y. $X' = Y - (X - Y)$.

4.5 Segments

4.5.1 Intersection

- Treat segments as lines.
- If $d \neq 0$, compute line intersection (x, y).
- Segments intersect iff

$$\min(x_1, x_2) \leq x \leq \max(x_1, x_2)$$
$$\min(y_1, y_2) \leq y \leq \max(y_1, y_2)$$

```java
boolean intersects(Point p1, Point p2, Point p3,
    Point p4) {
  double o1 = orient(p1, p2, p3);
  double o2 = orient(p1, p2, p4);
  double o3 = orient(p3, p4, p1);
  double o4 = orient(p3, p4, p2);
  // check first condition of the lemma
  if(o1 * o2 < 0 && o3 * o4 < 0) return true;
  // check seconds condition of the lemma
  if(o1 == 0 && inBox(p1, p2, p3)) return true;
  if(o2 == 0 && inBox(p1, p2, p4)) return true;
  if(o3 == 0 && inBox(p3, p4, p1)) return true;
  if(o4 == 0 && inBox(p3, p4, p2)) return true;
  return false;
}
```

4.5.2 Intersections problem

Given a lot of segments, return true if it exists a pair that intersects.

```java
boolean segmentIntersection(Segment[] S) {
  Event[] events = new Event[2 * S.length];
  // create event points
  for(int i = 0, j = 0; i < S.length; i++) {
    events[j++] = new Event(S[i].l.x, true, S[i]);
    events[j++] = new Event(S[i].r.x, false, S[i]);
  }
  Arrays.sort(events);
  SegmentCmp cmp = new SegmentCmp();
  TreeSet&lt;Segment&gt; T = new TreeSet&lt;Segment&gt;(cmp);
  // sweep line
  for(Event event : events) {
    Segment s = event.s;
    cmp.x = event.x;
    if(event.isLeft) {
      // new segment found. check if it intersects
    one of its neighbors
      T.add(s);
      Segment above = T.higher(s);
      Segment bellow = T.lower(s);
      if((above != null && intersects(above, s)) ||
         (bellow != null && intersects(bellow, s)))
        return true;
    } else {
      // end of segment. check if its neighbors
    intersect
      Segment above = T.higher(s);
      Segment bellow = T.lower(s);
      if(above != null && bellow != null &&
    intersects(above, bellow))
        return true;
      T.remove(s);
    }
  }
  return false;
}

class Event implements Comparable<Event> {
  double x;
  boolean isLeft;
  Segment s;
  public Event(double x, boolean isLeft, Segment s)
    {
    this.x = x;
    this.isLeft = isLeft;
    this.s = s;
  }
  public int compareTo(Event other) {
    int cmp = Double.compare(x, other.x);
    // ensure that left comes before right
    if(cmp == 0) return isLeft? -1 : 1;
    return cmp;
  }
  public String toString() {
    return x + " " + isLeft;
```

```java
  }
}

class SegmentCmp implements Comparator&lt;Segment&gt; {
  double x;
  public int compare(Segment s1, Segment s2) {
    // compute A,B,C from eq Ax + by = C for each
    segment
    double A1 = s1.r.y - s1.l.y;
    double B1 = s1.l.x - s1.r.x;
    double C1 = A1 * s1.l.x + B1 * s1.l.y;

    double A2 = s2.r.y - s2.l.y;
    double B2 = s2.l.x - s2.r.x;
    double C2 = A2 * s2.l.x + B2 * s2.l.y;

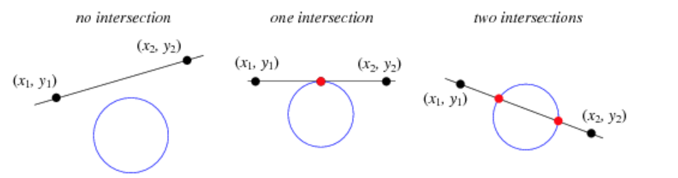
    // no divisions =)
    double t1 = B2 * (C1 - A1 * x);
    double t2 = B1 * (C2 - A2 * x);
    if(t1 == t2) {
      return s1 == s2? 0 : -1;
    } else if(B1 * B2 > 0) {
      return Double.compare(t1, t2);
    } else {
      return Double.compare(t2, t1);
    }
  }
}
```

4.6 Circles

4.6.1 Circles from 3 points

- 3 non collinear points define a unique circle.
- Center is intersection of bisectors of XY and YZ.

4.6.2 Circle-line intersection



$$d_x = x_2 - x_1$$
$$d_y = y_2 - y_1$$
$$d_r = \sqrt{d_x^2 + d_y^2}$$
$$D = \begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix} = x_1\, y_2 - x_2\, y_1$$

$$x = \frac{D\, d_y \pm \operatorname{sgn}^*(d_y)\, d_x \sqrt{r^2\, d_r^2 - D^2}}{d_r^2}$$
$$y = \frac{-D\, d_x \pm |d_y| \sqrt{r^2\, d_r^2 - D^2}}{d_r^2},$$

$$\operatorname{sgn}^*(x) \equiv \begin{cases} -1 & \text{for } x < 0 \\ 1 & \text{otherwise.} \end{cases}$$

$$\Delta \equiv r^2\, d_r^2 - D^2$$

Δ	incidence
$\Delta < 0$	no intersection
$\Delta = 0$	tangent
$\Delta > 0$	intersection

4.6.3 Circle-circle or circle-point tangents

Find lines tangent to both circles (C_1, r_1) and (C_2, r_2). Let $d = |C_1C_2|$.

- **Inner tangents:** Condition: $r_1 + r_2 \leq d$ (if equal, only one). Let $\alpha = \operatorname{acos}(\frac{r_1+r_2}{d})$, then the tangency two points T on either circle are such that $\widehat{C_2C_1T} = \alpha$ and $\widehat{C_1C_2T} = \alpha$ respectively.
- **Outer tangents:** Condition: $|r_1 - r_2| \leq d$ (if equal, only one). Same, but with $\widehat{C_2C_1T} = \operatorname{acos}(\frac{r_1-r_2}{d})$ and $\widehat{C_1C_2T} = \operatorname{acos}(\frac{r_2-r_1}{d})$.

For circle-point tangents, set $r_2 = 0$ on inner tangents.

4.7 Polygons

4.7.1 Triangulation

A vertex i of a polygon is a ear if the triangle formed by vertices $i-1$, i and $i+1$ is inside the polygon. Every polygon has at least two ears. Therefore to triangulate we can remove the ears until only a triangle remains. Any triangulation has always exactly $n-2$ triangles. Implemented naivelly this gives a $O(n^3)$ algorithm. Can be implemented in $O(n^2)$. Faster algorithms exists: sweep line does it in $O(n\log(n))$ but is it harder.

```java
// assumes that pol is in counter-clockwise order
private static boolean ear(Point[] pol, int i) {
  int n = pol.length;
  int j = (i - 1 + n) % n;
  int k = (i + 1 + n) % n;
  // if ccw then points must also be ccw
  if(orient(pol[j], pol[i], pol[k]) < eps) return
    false;
  for(int m = 0; m < n; m++)
    // inTriangle not in the sheets. checks if pol[m
    ] is inside triangle pol[j]pol[i]pol[k]
    if(m != i && m != j && m !=k && inTriangle(pol[m
    ], pol[j], pol[i], pol[k]))
      return false;
  return true;
}
```

4.7.2 Triangles

- côtés a, b, c, angles A, B, C, hauteurs h_A, h_B, h_C, $s = \frac{a+b+c}{2}$, aire S.
- Aire: $S = ah_A/2$, $S = ab\sin C/2$, $S = \sqrt{s(s-a)(s-b)(s-c)}$.
- Inradius $r = \frac{S}{s}$.
- Outradius $2R = \frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}$.
- $rR = \frac{abc}{4s}$.

4.7.3 Check convexity

```java
boolean isConvex(Point[] P) {
  if(P.length < 3) return false;
  double o1 = orient(P[P.length-1], P[0], P[1]);
  for (int i = 0; i < P.length; i++) {
    double o2 = orient(P[i], P[i + 1], P[i + 2]);
    if(o1 * o2 < 0) {
      return false;
    } else if (o2 != 0) {
      o1 = o2;
    }
  }
  return true;
}
```

4.7.4 Winding number

Number of times a path of points "turn around" another point. (can check if a point is inside a polygon: in this case, winding numbe ! = 0)

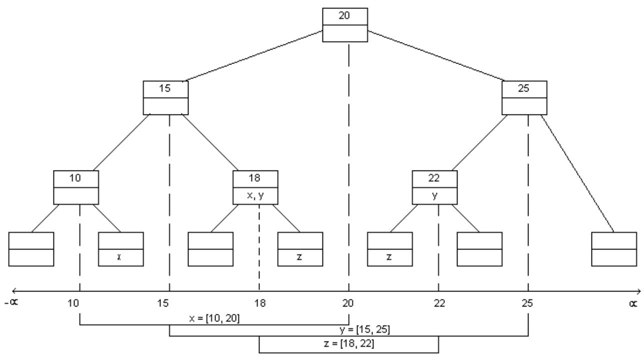
```java
// assumes p is not on P
double winding(Point[] P, Point p) {
  //make a translation so p = (0, 0)
  for(Point q : P) {
    q.x -= p.x;
    q.y -= p.y;
  }
  double w = 0;
  for(int i = 0; i < P.length - 1; i++) {
    if(P[i].y * P[i + 1].y < 0) {
      // segment crosses the x-axis
      double r = (P[i].y - P[i+1].y) * P[i].x + P[i
    ].y * (P[i+1].x - P[i].x);
      //check for intersection with the positive x-
    axis
      if((P[i].y - P[i+1].y > 0 && r > 0) || (P[i].y
     - P[i+1].y < 0 && r < 0)) {
        // segment fully crosses the x-axis
        // - to + add 1, + to - subtract 1
        w += P[i].y < 0? 1 : -1;
      } else if(P[i].y == 0 && P[i].x > 0) {
        // the segment starts at the x-axis
        // 0 to + add 0.5, 0 to - subtract 0.5
        w += P[i+1].y > 0? 0.5 : -0.5;
      } else if(P[i+1].y == 0 && P[i+1].x > 0) {
        // the segment ends at the x-axis
        // - to 0 add 0.5, + to 0 subtract 0.5
        w += P[i].y < 0? 0.5 : -0.5;
      }
    }
  }
  return w;
}
```

4.7.5 Convex Hull

```
Point[] convexHull(Point[] points) {
  // sort points by increasing x coordinates
  Arrays.sort(points, new xComp());
  // build upper chain
  Point[] upChain = buildChain(points, 1);
  // build lower chain
  Point[] loChain = buildChain(points, -1);
  Point[] hull = new Point[upChain.length + loChain.
    length - 2];
  int i;
  // build convex hull from upper and lower chain
  for(i = 0; i < upChain.length; i++) {
    hull[i] = upChain[i];
  }
  for(int j = loChain.length - 2; j >= 1; j--) {
    hull[i] = loChain[j]; i++;
  }
  return hull;
}

Point[] buildChain(Point[] points, int sgn) {
  Point[] S = new Point[points.length];
  int k = 0;
  S[k++] = points[0]; // push points[0]
  S[k++] = points[1]; // push points[1]
  // build chain
  for(int i = 2; i < points.length; i++) {
    //double orient = orient(S[k - 2], S[k - 1],
    points[i]);
    while(k >= 2 && sgn * orient(S[k - 2], S[k - 1],
     points[i]) >= 0) {
      S[k - 1] = null; // pop
      k--;
    }
    S[k++] = points[i]; // push points[i]
  }
  return Arrays.copyOf(S, k);
}
```

4.8 Interval Tree



```
class IntervalTree {
  Node root;
  public IntervalTree(int[] x) {
    root = new Node();
    buildTree(root, 0, x.length - 1, x);
  }
  public int measure() {
    return root.measure;
  }
  public void buildTree(Node node, int i, int j, int
    [] x) {
    if(j - i == 1) {
      node.l = x[i];
      node.r = x[j];
      node.m = -1;
    } else {
      node.l = x[i];
      node.r = x[j];
      int mid = (i + j) / 2;
      Node left = new Node();
      buildTree(left, i, mid, x);
      Node right = new Node();
      buildTree(right, mid, j, x);
      node.m = x[mid];
      node.left = left;
      left.parent = node;
      node.right = right;
      right.parent = node;
    }
  }
  public void remove(int x1, int x2) {
    remove(root, x1, x2);
  }
  private void remove(Node node, int x1, int x2) {
    if(node.l == x1 && node.r == x2) {
      node.count = Math.max(0, node.count - 1);
      if(node.left == null || node.right == null) {
        node.measure = node.count == 0 ? 0 : node.
  measure;
      } else {
        node.measure = node.count == 0 ? node.left.
  measure + node.right.measure : node.measure;
      }
   } else {
      // go down the three to delete new interval
      int mid = node.m;
      if(x1 < mid && mid < x2) {
        // split
        remove(node.left, x1, mid);
        remove(node.right, mid, x2);
      } else if(node.l <= x1 && x2 <= mid) {
        // contained on left
        remove(node.left, x1, x2);
      } else {
        // contained on right
        remove(node.right, x1, x2);
      }
      // update measures when going up
      if(node.count == 0) {
        node.measure = node.left.measure + node.
  right.measure;
      }
    }
  }
  public void add(int x1, int x2) {
    add(root, x1, x2);
  }
  private void add(Node node, int x1, int x2) {
    if(node.l == x1 && node.r == x2) {
      node.measure = x2 - x1;
      node.count++;
    } else {
      // go down the three to add new interval
      int mid = node.m;
      if(x1 < mid && mid < x2) {
        // split
        add(node.left, x1, mid);
        add(node.right, mid, x2);
      } else if(node.l <= x1 && x2 <= mid) {
        // contained on left
        add(node.left, x1, x2);
      } else {
        // contained on right
        add(node.right, x1, x2);
      }
      // update measures when going up
      if(node.count == 0) {
        node.measure = node.left.measure + node.
  right.measure;
      }
    }
  }
  public class Node {
    int l, r, m;
    int count, measure;
    Node left, right, parent;
  }
}
```

4.9 Area of union of rectangles

```
long area(R[] r) {
```

```
  // sort y coordinates
  int[] y = new int[2 * r.length];
  int k = 0;
  for(R rect : r) {
    y[k++] = rect.y1;
    y[k++] = rect.y2;
  }
  Arrays.sort(y);
  // build interval tree
  IntervalTree T = new IntervalTree(y);
  // initialize event queue
  PriorityQueue<Event> Q = new PriorityQueue<Event
    >();
  for(R rectangle : r) {
    Q.add(new Event(rectangle.x1, rectangle));
    Q.add(new Event(rectangle.x2, rectangle));
  }
  long area = 0;
  Event previous = null;
  // loop over all events
  while(!Q.isEmpty()) {
    // poll next event
    Event e = Q.poll();
    if(previous == null) {
      // first vertical line
      T.add(e.r.y1, e.r.y2);
    } else {
      // found a new vertical line
      // update area by dx * tree measure
      int dx = e.x - previous.x;
      area += dx * T.measure();
      if(e.x == e.r.x1) {
        // new rectangle, add segment to T
        T.add(e.r.y1, e.r.y2);
      } else {
        // exiting rectangle, remove segment from T
        T.remove(e.r.y1, e.r.y2);
      }
    }
    // update previous
    previous = e;
  }
  return area;
}

class Event implements Comparable<Event> {
  int x;
  R r;
  public Event(int x, R r) {
    this.x = x;
    this.r = r;
  }
  public int compareTo(Event other) {
    return x - other.x;
  }
}
class R {
  int x1, y1, x2, y2;
  public R(int x1, int y1, int x2, int y2) {
    this.x1 = x1; this.y1 = y1; this.x2 = x2; this.y2 =
     y2;
  }
}
```

5 Geometry in 3D

5.1 Cross product

With vectors $\tilde{V_1} = (a_1, b_1, c_1)$ and $\tilde{V_2} = (a_2, b_2, c_2)$:

$$\tilde{V_1} \times \tilde{V_2} = (b_1c_2 - c_1b_2, c_1a_2 - a_1c_2, a_1b_2 - b_1a_2)$$

5.2 Equation of a plane

5.2.1 with a normal vector and a point

A plane is defined by a point (x_0, y_0, z_0) and an normal vector (a, b, c).

$$a(x - x_0) + b(y - y_0) + c(z - z_0) = 0$$

$$ax + by + cz = ax_0 + by_0 + cz_0 = d$$

5.2.2 with a point and two vectors in the plane

A plane is defined by a point (x_0, y_0, z_0) and two vectors $(\alpha_1, \beta_1, \gamma_1)$ and $(\alpha_2, \beta_2, \gamma_2)$. We obtain the parametric equations:

$$x = x_0 + t_1\alpha_1 + t_2\alpha_2$$
$$y = y_0 + t_1\beta_1 + t_2\beta_2$$
$$z = z_0 + t_1\gamma_1 + t_2\gamma_2$$

Or we can find the normal vector of the plane by doing the vector product of the two vectors

5.2.3 with three points

Make vectors from these three points and use one of the methods above.

5.3 Equation of a line

5.3.1 With a point and a vector

A line is defined by a point (x_0, y_0, z_0) and a vector (a, b, c).

$$x = x_0 + ta$$
$$y = y_0 + tb$$
$$z = z_0 + tc$$

5.3.2 With two points

$$x = x_1 + t(x_2 - x_1)$$
$$y = y_1 + t(y_2 - y_1)$$
$$z = z_1 + t(z_2 - z_1)$$

5.4 Distance from a point to a line

Distance from a point $M_P = (x_p, y_p, z_p)$ to a line defined with a point $M_L = (x_l, y_l, z_l)$ and a vector $\tilde{V} = (a, b, c)$ equals to

$$\frac{||M_L\tilde{M}_P \times \tilde{V}||}{||\tilde{V}||}$$

5.5 Distance from a point to a plane

The distance to a plane is 0 if a point is in the plane.

$$\frac{|ax_p + by_p + cz_p - d|}{\sqrt{a^2 + b^2 + c^2}}$$

5.6 Orthogonal projection of a point on a line

If p_p is the point, s the direction vector of the line and p_l the base point for the vector, the projection is

$$\frac{(p_p - p_l) \cdot s}{s \cdot s} s + p_l$$

5.7 Orthogonal projection of a point on a plane

$$P_p = (x + \lambda a, y + \lambda b, z + \lambda c)$$
$$\lambda = -\frac{ax_p + by_p + cz_p - d}{a^2 + b^2 + c^2}$$

5.8 Orthogonal projection of a line on a plane

Take two points of the line, project them on the plane, recreate the line from the two new points.

5.9 Finding if a point is in a 3D polygon

Take any ray in the plane of the polygon, starting from the point you want to check (simply fix one of the coordinate of the point to find the ray); if it intersects an even number number of time with the sides of the polygon, the point is inside it.

5.10 Intersection of a line and a plane

Given a plane $ax + by + cz = d$ and a line with parametric equations: $x = x_0 + \alpha t$, $y = y_0 + \beta t$, $z = z_0 + \gamma t$ The value of t associated with the intersection is

$$t = \frac{d - ax_0 - by_0 - cz_0}{a\alpha + b\beta + c\gamma}$$

6 Math

6.1 Permutations, Combinations, Arrangements... *untested*

```
void nextPerm(int[] p) {
  int n = p.length;
  int k = n - 2;
  while(k >= 0 && p[k] >= p[k + 1]) {k--;}
  int l = n - 1;
  while(p[k] >= p[l]) {l--;}
  swap(p, k, l);
  reverse(p, k + 1, n);
}

LinkedList<Integer> getPermutation(int n, int index
    ) {
  LeftRightArray lr = new LeftRightArray(n);
  lr.freeAll();
  LinkedList<Integer> perm = new
  LinkedList<Integer>();
  getPermutation(lr, index, fact(n), perm);
  return perm;
}

void getPermutation(LeftRightArray lr, int i, long
    fact, LinkedList<Integer> perm) {
  int n = lr.size();
  if(n == 1) {
    perm.add(lr.freeIndex(0, false));
  } else {
    fact /= n;
    int j = (int)(i / fact);
    perm.add(lr.freeIndex(j, true));
    i -= j * fact;
    getPermutation(lr, i, fact, perm);
  }
}

int[] getICombinadic(int n, int k, long i) {
  int[] comb = new int[k];
  int j = 0;
  for(int z = 1; z <= n; z++) {
    if ( k == 0 ) {
      break;
    }
    long threshold = C(n - z, k - 1);
    if (i < threshold) {
      comb[j] = z - 1;
      j++;
      k = k - 1;
    } else if (i >= threshold) {
      i = i - threshold;
    }
  }
  return comb;
}

void combinations(int n, int k) {

}

void combinations(int n, int j, int[] comb, int k) {
  if(k == comb.length) {
    System.out.println(Arrays.toString(comb));
  } else {
    for(int i = j; i < n; i++) {
      comb[k] = i;
      combinations(n, i + 1, comb, k + 1);
    }
  }
}
void subsets(int[] set) {
  int n = (1 << set.length);
  for(int i = 0; i < n; i++) {
    int[] sub = new int[Integer.bitCount(i)];
    int k = 0, j = 0;
    while((1 << j) <= i) {
      if((i & (1 << j)) == (1 << j)) {
        sub[k++] = set[j];
      }
      j++;
    }
    System.out.println(Arrays.toString(sub));
  }
}
```

6.2 Decomposition in unit fractions *untested*

Write $0 < \frac{p}{q} < 1$ as a sum of $\frac{1}{k}$

```
void expandUnitFrac(long p, long q) {
  if(p != 0) {
    long i = q % p == 0 ? q/p : q/p + 1;
    System.out.println("1/" + i);
    expandUnitFrac(p*i-q, q*i);
  }
}
```

6.3 Combination

Number of combinations of k elements within n ones (C_n^k)
Special case : $C_n^k \mod 2 = n \oplus m$

```
long C(int n, int k) {
  double r = 1;
  k = Math.min(k, n - k);
  for(int i = 1; i <= k; i++)
  r /= i;
  for(int i = n; i >= n - k + 1; i--)
  r *= i;
  return Math.round(r);
}
```

6.3.1 Catalan numbers

$\text{cat}(n) = \frac{C_n^{2n}}{n+1}$ $\text{cat}(n+1) = \frac{(2n+2)(2n+1)}{(n+2)(n+1)}\text{cat}(n)$

- distinct binary trees with n vertices.
- expressions containing n pairs of parentheses correctly matched (e.g. $n = 3$ ()()(), ()(()), (())(), ((())), (()())).
- parenthesize $n+1$ factors (e.g. $n = 3$ $(ab)(cd)$, $a(b(cd))$, $((ab)c)(d)$, $(a(bc))$
- triangulate a convex polygon of $n + 2$ sides.
- number of monotonic paths along the edge of a $n \times n$ grid which do not pass above de diagonal.

Compute all Catalan number $\le n$

```
long[] allCatalan(int n) {
  long[] catalanNumbers = new long[n];
  catalanNumbers[0] = 1;
  for(int i = 1; i < n; i++) {
    int j = i - 1;
    long b = j * j;
    long a = 4 * b + 6 * j + 2;
    b += 3 * j + 2;
    catalanNumbers[i] = catalanNumbers[j] * a/b;
  }
  return catalanNumbers;
}
```

6.4 Fibonacci series

$f(0) = 0$, $f(1) = 1$ et $f(n) = f(n-1) + f(n-2)$.
The following relation enables us to compute every number of the series in $O(log(n))$:

$$\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}^n = \begin{pmatrix} f_{n+1} & f_n \\ f_n & f_{n-1} \end{pmatrix}$$

6.5 Cycle finding

```
int[] floydCycleFinding (int x0) {
  int tortoise = f(x0), hare = f(f(x0));
  while (tortoise != hare) {
    tortoise = f(tortoise);
    hare = f(f(hare)); }
  int mu = 0; hare = x0; // first
  while (tortoise != hare) {
    tortoise = f(tortoise); hare = f(hare); mu++; }
```

```
  int lambda = 1; hare = f(tortoise); // length
  while (tortoise != hare) {
    hare = f(hare); lambda++; }
  return new int[] {mu, lambda};
}
```

6.6 Number theory

6.6.1 Misc

$$ax \le b \Leftrightarrow x \le \left\lfloor \frac{b}{a} \right\rfloor \quad ax \ge b \Leftrightarrow x \le \left\lceil \frac{b}{a} \right\rceil \quad \left\lceil \frac{a}{b} \right\rceil = \left\lfloor \frac{a+b-1}{b} \right\rfloor.$$

```
long gcd (long a, long b) {
  return (b == 0) ? a : gcd(b, a % b);
}
long lcm (long a, long b) {
  return a * (b / gcd(a,b));
}
long modInverse (long a, long b) {
  return big(a).modInverse(big(b)).longValue();
}
long modInverse (long a, long b) {
  extendedEuclid(a, b);
  return x;
}
```

In prime factorization of n, the power of p is

$$\sum_{i=1}^{\infty} \left\lfloor \frac{n}{p^i} \right\rfloor$$

```
int factopower (int n, int p) {
  int pow = 0;
  while (n > 0) {
    pow += n / p;
    n /= p;
  }
  return pow;
}
```

6.6.2 Équations diophantiennes

$ax + by = c$. $d = \gcd(a, b)$, no sol si d divise pas c sinon $(a, b) = (x(n/d) + (b/d)n, y(n/d) + (a/d)n)$ où $ax + by = d$ $n \in \mathbb{Z}$.

```
static int x, y;
static int extendedEuclid(int a, int b) {
  if (b == 0) { x = 1; y = 0; return a; }
  int d = extendedEuclid(b, a % b);
  int x1 = y;
  int y1 = x - (a / b) * y;
  x = x1;
  y = y1;
  return d;
}
```

6.6.3 Chinese remainder theorem

```
static long[] chinese (long[] b, long[] m) {
  long x = b[0], l = m[0];
  for (int i = 1; i < m.length; i++) {
    long m1 = m[i], b1 = b[i];
    long d = gcd(l, m1);
    if ((x - b1) % d != 0) return null;
    long lcm = l * (m1 / d);
    long t1 = ((((x - b1) / d) % lcm) * (modInverse(
    m1/d, l/d) % lcm)) % lcm;
    x = (b1 + ((t1 * m1) % lcm)) % lcm;
    l = lcm;
  }
  return new long[] {x, l};
}
```

6.6.4 Euler phi

$\phi(N) = N \times \prod_{p|N}(1 - \frac{1}{p}) = \#\{k < N | \gcd(k, N) = 1\}$

```
long phi(long n, int primes[]) {
  long ans = n; // Method 1
  for (int i = 0; i < primes.length && primes[i] *
    primes[i] <= n; i++) {
    int p = primes[i];
    if (n % p == 0) ans -= ans / p;
    while (n % p == 0) ans /= p;
  }
  if (n != 1) ans -= ans / n;
  return ans;
}
for (int i = 1; i <= 1000000; i++) phi[i] = i;
for (int i = 2; i <= 1000000; i++) // Method 2
  if (phi[i] == i) // i is prime
    for (int j = i; j <= 1000000; j += i)
      phi[j] = (phi[j] / i) * (i - 1);
```

- If $\phi(1) = 1$, $n = \sum_{d|n} \phi(d)$.
- p prime iff there exists a number relatively prime with p of order $p - 1$ (primitive root of p).
- There is $\phi(d)$ number of orders d modulo p.
- If g is order d mod p, $\{g^k | k = 1, \dots, d-1 : (k, d) = 1\}$ are the $\phi(d)$ numbers of order d mod p.

Let $\phi_S(n) = \sum_{i=1}^{n} \phi(i)$.

$$\phi_S(n) = \frac{n^2+n}{2} - \sum_{d=2}^{n} \phi_S\left(\left\lfloor \frac{n}{d} \right\rfloor\right).$$

Discrete log

$$\begin{aligned} a^x \equiv a^y \pmod{n} &\Leftrightarrow x \equiv y \pmod{O_n(a)} \\ &\Leftarrow x \equiv y \pmod{\phi(n)} \end{aligned}$$

and in particular, if g is a primitive root of p,

$$g^x \equiv g^y \pmod{p} \Leftrightarrow x \equiv y \pmod{p-1}$$

so for an equation $(p \not| a, b)$

$$a^{k_1} \equiv b^{k_2} \pmod{p}$$

we take ℓ_1 and ℓ_2 such that $a = g^{\ell_1}$ and $b = g^{\ell_2}$ and it becomes

$$k_1\ell_1 \equiv k_2\ell_2 \pmod{p-1}$$

6.6.5 Quadratic residue (QR)

p *odd* prime. Let g primitive root mod p. $\forall n$, g^{2n} is QR mod p and g^{2n+1} is not. There is $\frac{p-1}{2}$ QR and $\frac{p-1}{2}$ not QR.

$$\begin{aligned} \left(\frac{a}{p}\right) &\equiv a^{\frac{p-1}{2}} \pmod{m} \\ &= \prod_{r=1}^{\frac{p-1}{2}} \varepsilon(ar) \end{aligned}$$

where $\varepsilon(x) = 1$ if $x \equiv 1, \dots, \frac{p-1}{2} \pmod{p}$ and -1 otherwise.
b odd ($\left(\frac{a}{b}\right) = 1$ does not mean a QR mod b !!!)

$$\left(\frac{a}{b}\right) \triangleq \prod \left(\frac{a}{p_i}\right)^{e_i}$$

- $\left(\frac{-1}{b}\right) = 1$ iff $b \equiv 1 \pmod{4}$.
- $\left(\frac{2}{b}\right) = 1$ iff $b \equiv \pm 1 \pmod{8}$.

b odd

$$\left(\frac{ac}{b}\right) = \left(\frac{a}{b}\right)\left(\frac{c}{b}\right)$$

a, b odd

$$\left(\frac{a}{b}\right)\left(\frac{b}{a}\right) = (-1)^{\frac{a-1}{2}\frac{b-1}{2}}.$$

```

}
```

6.7 Linear equations

Solve $Ax = b$.

```java
double[] gaussElim(double[][] A, double[] b) {
  int N = b.length;
  for(int p = 0; p < N; p++) {
    int max = p;
    for(int i = p + 1; i < N; i++) {
      if(Math.abs(A[i][p])>Math.abs(A[max][p])) {
        max = i;
      }
    }
    swap(A, p, max);
    swap(b, p, max);
    // singular or nearly singular
    if(Math.abs(A[p][p]) <= E) {
      return null;
    }
    // pivot within A and b
    for(int i = p + 1; i < N; i++) {
      double alpha = A[i][p] / A[p][p];
      b[i] -= alpha * b[p];
      for(int j = p; j < N; j++) {
        A[i][j] -= alpha * A[p][j];
      }
    }
  }
  // back substitution
  double[] x = new double[N];
  for(int i = N - 1; i >= 0; i--) {
    double sum = 0.0;
    for(int j = i + 1; j < N; j++) {
      sum += A[i][j] * x[j];
    }
    x[i] = (b[i] - sum) / A[i][i];
  }
  return x;
}
```

6.8 Ternary Search

Find minimum of unimodal function.

```java
double ternarySearch(double left, double right) {
  if(right - left < E) {
```

```
    return (right + left) / 2;
  }
  double leftThird = (left * 2 + right) / 3;
  double rightThird = (left + right * 2) / 3;
  //minimize >, maximize <
  if(f(leftThird) > f(rightThird)) {
    return ternarySearch(leftThird, right);
  }
  return ternarySearch(left, rightThird);
}
```

6.9 Integration

Compute integral.

```
double integral(double a, double b) {
  double h = b - a;
  double c = (a + b) / 2.0;
  double d = (a + c) / 2.0;
  double e = (b + c) / 2.0;
  double Q1 = h/6  * (f(a) + 4*f(c) + f(b));
  double Q2 = h/12 * (f(a)+4*f(d)+2*f(c)+4*f(e)
                +f(b));
  if (Math.abs(Q2 - Q1) <= E) {
    return Q2 + (Q2 - Q1) / 15;
  } else {
    return integral(a, c) + integral(c, b);
  }
}
```

7 Strings

7.1 Longest palindrome

```
int[] calculateAtCenters(String s) {
  int n = s.length();
  int[] L = new int[2 * n + 1];
  int i = 0, palLen = 0, k = 0;
  while(i < n) {
    if((i > palLen) &&
      (s.charAt(i - palLen - 1)==s.charAt(i))) {
      palLen += 2;
      i += 1;
      continue;
    }
    L[k++] = palLen;
    int e = k - 2 - palLen;
    boolean found = false;
    for(int j = k - 2; j > e; j--) {
      if(L[j] == j - e - 1) {

  return s.substring(b, e);
}

String getPalindrome(String s)
{
  return getPalindrome(s, calculateAtCenters(s));
}
```

7.2 Occurences in a string

KMP(s,p) returns occurences index of p in s.

```
int[] kmpPreprocess(char[] p) {
  int m = p.length;
  int[] b = new int[m+1];
  int i = 0, j = -1; b[0] = -1; // starting values
  while (i < m) { // pre-process the pattern string
    p
    while (j >= 0 && p[i] != p[j]) j = b[j]; // if
    different, reset j using b
    i++; j++; // if same, advance both pointers
    b[i] = j;
  }
  return b; }

LinkedList<Integer> kmpSearchAll(char[] s, char[] p)
    { // text, pattern
  int[] b = kmpPreprocess(p); // back table
  int n = s.length, m = p.length;
  LinkedList<Integer> found = new LinkedList<Integer
    >();
  int i = 0, j = 0; // starting values
  while (i < n) { // search through string s
    while (j >= 0 && s[i] != p[j]) j = b[j]; // if
    different, reset j using b
    i++; j++; // if same, advance both pointers
    if (j == m) { // a match found when j == m
      found.add(i-j);
      j = b[j]; // prepare j for the next possible
    match
    } }
  return found; }

int kmpSearchFirst(char[] s, char[] p) { // text,
    pattern
  int[] b = kmpPreprocess(p); // back table
  int n = s.length, m = p.length;
  int i = 0, j = 0; // starting values
  while (i < n) { // search through string s
    while (j >= 0 && s[i] != p[j]) j = b[j]; // if
    different, reset j using b
    i++; j++; // if same, advance both pointers
    if (j == m) { // a match found when j == m
      return i - j;
    } }
  return n - j; }
```

7.3 Multipattern search: Aho-Corasick

The complexity is the sum of the lengths of the patterns + the length of the text + the sum of the matches of each pattern in other patterns.

```
static class Node {
  Node[] next;
  Node fall_node;
  LinkedList<Integer> pattern_ids;
  public Node(int alphabet_len) {
    next = new Node[alphabet_len];
    fall_node = null;
    pattern_ids = null;
  }
}
static int next_id = 0;
static int TrieInsert(Node node, int p[], int
    alphabet_len) {
  for (int i = 0; i < p.length; i++) {
    if (node.next[p[i]] == null)
```

```
      node.next[p[i]] = new Node(alphabet_len);
    node = node.next[p[i]];
  }
  int cur_id;
  if (node.pattern_ids == null) {
    cur_id = next_id++;
    node.pattern_ids = new LinkedList<Integer>();
    node.pattern_ids.add(cur_id);
  } else {
    cur_id = node.pattern_ids.getFirst();
  }
  return cur_id;
  // two identical patterns have the same id
}
static Node BuildTrie(ArrayList<int[]> patterns, int
    [] ids, int alphabet_len) {
  Node trie_root = new Node(alphabet_len);

  // Insert pattern lines in the trie.
  for (int i = 0; i < patterns.size(); i++)
    ids[i] = TrieInsert(trie_root, patterns.get(i),
    alphabet_len);

  // Build fall function.
  LinkedList<Node> q = new LinkedList<Node>();
  for (int i = 0; i < alphabet_len; i++)
    if (trie_root.next[i] == null)
      trie_root.next[i] = trie_root;  // Complete
    the next function for the root.
    else {
      q.add(trie_root.next[i]);
      trie_root.next[i].fall_node = trie_root;
    }
  while (!q.isEmpty()) {
    Node cur = q.poll();
    if (cur.fall_node.pattern_ids != null) {
      if (cur.pattern_ids == null)
        cur.pattern_ids = new LinkedList<Integer>();
      cur.pattern_ids.addAll(cur.fall_node.
    pattern_ids);
    }
    for (int i = 0; i < alphabet_len; i++)
      if (cur.next[i] != null) {
        q.add(cur.next[i]);
        Node v = cur.fall_node;
        while (v.next[i] == null)
          v = v.fall_node;
        cur.next[i].fall_node = v.next[i];
      }
  }
  return trie_root;
}
static LinkedList<Integer>[] AhoCorasickSearch(Node
    trie_root, int[] text) {
  LinkedList<Integer>[] match = new LinkedList[text.
    length];
  Node cur = trie_root;
  for (int i = 0; i < text.length; i++) {
    int ind = text[i];
    while (cur.next[ind] == null) {
      cur = cur.fall_node;
    }
    cur = cur.next[ind];
    match[i] = cur.pattern_ids;
  }
  return match;
}
```

7.4 Match with hash: Rabin-Karp

```
static final long MOD  = 2147483647;
static final long BASE = 2;

static int RabinKarp(int[] p, int[] s) {
  if (s.length < p.length) return -1;
  int m = p.length, n = s.length;
  long phash = 0;
  long hash = 0;

```

8 Miscellaneous

8.1 FFT

Efficiently compute the coefficients of the polynomial

$$(\sum_{i=0}^{n} a_i x^i)(\sum_{i=0}^{n} b_i x^i)$$

That is, compute the convolution

$$c_k = a \otimes b = \sum_{i=0}^{k} a_i b_{k-i}.$$

For any two vectors a and b of length n that is a power of two,

$$a \otimes b = \mathrm{DFT}_{2n}^{-1}(\mathrm{DFT}_{2n}(a) \cdot \mathrm{DFT}_{2n}(b)).$$

where a and b are padded with 0s to length $2n$, $\cdot$ denotes the componentwise product and DFT is $n\log(n)$!

```
public static void fft(double[] re, double[] im,
    boolean invert) {
